Received 14 December 2007; accepted 4 January 2008

Key indicators: single-crystal X-ray study;  $T = 296$  K; mean  $\sigma(C-C) = 0.003$  Å;  
R factor = 0.030; wR factor = 0.068; data-to-parameter ratio = 18.7.

The title compound,  $[\text{Ni}(\text{N}_3)_2(\text{C}_6\text{H}_6\text{N}_2\text{O})_2]$ , was obtained as the first crystalline product from the reaction of  $\text{Ni}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ , picolinamide and  $\text{NaN}_3$  in aqueous media. After a few days in the mother liquor, crystals of the *cis* isomer transformed into the *trans* isomer [Đaković & Popović (2007). *Acta Cryst. C*63, m507–m509]. The Ni atom exhibits a distorted octahedral environment and contains two azide ions and two planar  $N,O$ -chelating picolinamide ligands, all *cis* related. The dihedral angle between the two chelate rings is 82.43 (7)°. Pairs of molecules are linked by  $\text{N}-\text{H}\cdots\text{N}$  hydrogen bonds into cyclic  $R_2^2(16)$  dimers, which are further packed into a three-dimensional framework by  $C(6)$  and  $C(8)$  chains by  $\text{N}-\text{H}\cdots\text{N}$  hydrogen bonds.

## Related literature

For information on the importance of azides in complexation, see Yuwen *et al.* (2000). A *trans* isomer of the title compound  $[\text{Ni}(\text{N}_3)_2(\text{C}_6\text{H}_6\text{N}_2\text{O})_2]$  has been reported by Đaković & Popović (2007). For related literature, see: Allen *et al.* (1987); Bernstein *et al.* (1995); Etter (1990).

#### **Comment**

This research is a part of our wider interest of the structural role of azide ions and of its metal complexes in metabolic processes of mitochondria (Yuwen *et al.*, 2000).

In the title compound Ni<sup>II</sup> atom lies in a general position and exhibits distorted octahedral environment (Fig. 1). The coordination sphere is composed by two *cis*-related *N,O*-chelating picolinamide and two azide ligands. The picolinamide ligands are bonded more tightly (Table 1) than in its *trans*-isomer (Đaković & Popović, 2007). All other bond lengths are comparable to the values reported for similar compounds (Allen *et al.*, 1987). The azide ligands are coordinated to the central metal ion in non-linear mode (123.7 (1) and 123.0 (1) $^\circ$ ) with the azide bond angles being 178.2 (2) and 176.9 (3) $^\circ$ .

The crystals of the title compound (I) are turquoise-green apart from the crystals of its *trans*-isomer which are olive-green.

The crystal structure (Fig 2) is stabilized by N—H···N hydrogen bond network between carboxamide groups and azide ligands. Typical amide N—H···O carboxamide dimers of  $R_2^2(8)$  found in *trans*-isomer are not observed in the *cis*-isomer. Instead, the amide N atoms, N2 and N4, are involved in two hydrogen bonds, forming  $R_2^2(16)$  rings, between two neighbouring molecules whereas C(8) chains along the axis c and C(6) chains along the axis b complete the network (Bernstein *et al.*, 1995; Etter, 1990).

The slightly smaller density of (I), and the fact that it is formed first and then transformed into its *trans*-isomer, suggests that (I) is the thermodynamically less stable isomer.

#### **Experimental**

The title compound was obtained by *in situ* reaction from Ni<sup>II</sup> nitrate hexahydrate, sodium azide and picolinamide in a 1:2:2 molar ratio. All starting substances were dissolved in water. The sodium azide solution was added in small portions with stirring into the solution mixture of the picolinamide and Ni<sup>II</sup> nitrate. In a few h the dark-green crystals of (I) were isolated. If the crystals are left in a mother liquor for a few days the dark-green crystals of (I) were transformed into the olive-green *trans*-isomer.

#### **Refinement**

Aromatic H atoms were fixed in geometrically idealized positions and refined using a riding model with [C—H = 0.93 Å and  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ ]. The amide H atoms were placed in the positions indicated by difference electron-density maps and their positions were allowed to refine together with individual isotropic displacement parameters.

## *Refinement*

Refinement on $F^2$	Secondary atom site location: difference Fourier map
Least-squares matrix: full	Hydrogen site location: inferred from neighbouring sites
$R[F^2 > 2\sigma(F^2)] = 0.030$	H atoms treated by a mixture of independent and constrained refinement
$wR(F^2) = 0.068$	$w = 1/[\sigma^2(F_o^2) + (0.0323P)^2]$ where $P = (F_o^2 + 2F_c^2)/3$
$S = 0.89$	$(\Delta/\sigma)_{\max} < 0.001$
4516 reflections	$\Delta\rho_{\max} = 0.43 \text{ e \AA}^{-3}$
242 parameters	$\Delta\rho_{\min} = -0.30 \text{ e \AA}^{-3}$
Primary atom site location: structure-invariant direct methods	Extinction correction: none

## *Special details*

**Geometry.** Bond distances, angles *etc.* have been calculated using the rounded fractional coordinates. All su's are estimated from the variances of the (full) variance-covariance matrix. The cell e.s.d.'s are taken into account in the estimation of distances, angles and torsion angles

**Refinement.** Refinement on  $F^2$  for ALL reflections except those flagged by the user for potential systematic errors. Weighted  $R$ -factors  $wR$  and all goodnesses of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The observed criterion of  $F^2 > \sigma(F^2)$  is used only for calculating - $R$ -factor-obs *etc.* and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
